## 1. Welcome to COPA-DATA help

#### **GENERAL HELP**

If you cannot find any information you require in this help chapter or can think of anything that you would like added, please send an email to documentation@copadata.com (mailto:documentation@copadata.com).

#### **PROJECT SUPPORT**

You can receive support for any real project you may have from our Support Team, who you can contact via email at support@copadata.com (mailto:support@copadata.com).

#### **LICENSES AND MODULES**

If you find that you need other modules or licenses, our staff will be happy to help you. Email sales@copadata.com (mailto:sales@copadata.com).

### 2. IEC62056

The driver implements the protocol C of the IEC 62056-21 specification, but only for reading.

Only values with address information will be represented.

# 3. IEC62056 - Data sheet

General:	
Driver file name	IEC62056.exe
Driver name	IEC-62056-21 Driver
PLC types	IEC 62056-21 or IEC 61107 compatible enrgy meter
PLC manufacturer	Siemens; IEC;

Driver supports:	
Protocol	IEC 62056-21; IEC 61107;
Addressing: Address-based	-
Addressing: Name-based	x
Spontaneous communication	-
Polling communication	х
Online browsing	-
Offline browsing	-
Real-time capable	-
Blockwrite	-
Modem capable	-
Serial logging	-
RDA numerical	-
RDA String	-

Requirements:	
Hardware PC	Standard network card or RS232 serial interface
Software PC	-
Hardware PLC	-
Software PLC	-
Requires v-dll	x

Platforms:	
Operating systems	Windows Vista, 7, 8, 8.1 Server 2008/R2, Server 2012/R2;
CE platforms	-;

# 4. Driver history

Date	Driver version	Change
20.08.08	200	Created driver documentation

### **DRIVER VERSIONING**

The versioning of the drivers was changed with zenon 7.10. There is a cross-version build number as of this version. This is the number in the 4th position of the file version,

For example: 7.10.0.4228 means: The driver is for version 7.10 service pack 0, and has the build number 4228.

Expansions or error rectifications will be incorporated into a build in the future and are then available form the next consecutive build number.

### BÞ

### **Example**

A driver extension was implemented in build 4228. The driver that you are using is build number 8322. Because the build number of your driver is higher than the build number of the extension, the extension is included. The version number of the driver (the first three digits of the file version) do not have any significance in relation to this. The drivers are version-agnostic

# 5. Requirements

This chapter contains information on the requirements that are necessary for use of this driver.

### 5.1 PC

For communication via TCP/IP:

A standard network card in the PC is required for communication.

For serial communication:

A serial interface at the PC is required. Alternatively, you can also use a COM port server or a USB/serial converter.

### 5.2 Control

The counter can be read out via the optical interface (tested with RS232 / TVS9 converter Landis & Gyr FDC1.3)

Alternatively, you can use a serial interface module. This was not tested, however.

Ethernet communication was tested with the CU-E20 Ethernet module by Landis & Gyr.

# 6. Configuration

In this chapter you will learn how to use the driver in a project and which settings you can change.

### Information

Find out more about further settings for zenon variables in the chapter Variables (main.chm::/15247.htm) of the online manual.

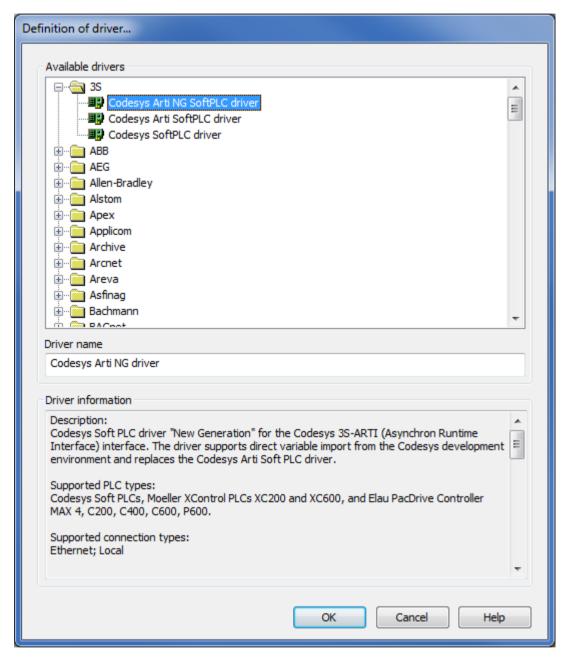

## 6.1 Creating a driver

In order to create a new driver:

1. Right-click on Driver in the Project Manage and select Driver new in the context menu.

2. In the following dialog the control system offers a list of all available drivers.

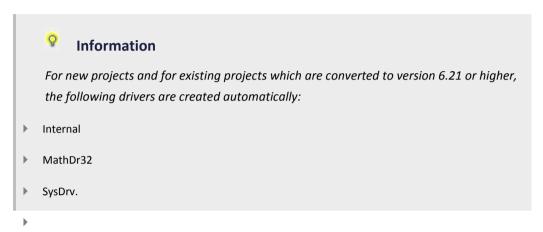

- 3. Select the desired driver and give it a name:
  - The driver name has to be unique, i.e. if one and the same driver is to be used several times in one project, a new name has to be given each time.
  - The driver name is part of the file name. Therefore it may only contain characters which are supported by the operating system. Invalid characters are replaced by an underscore (\_).

- Attention: This name cannot be changed later on.
- 4. Confirm the dialog with ox. In the following dialog the single configurations of the drivers are defined.

Only the respective required drivers need to be loaded for a project. Later loading of an additional driver is possible without problems.

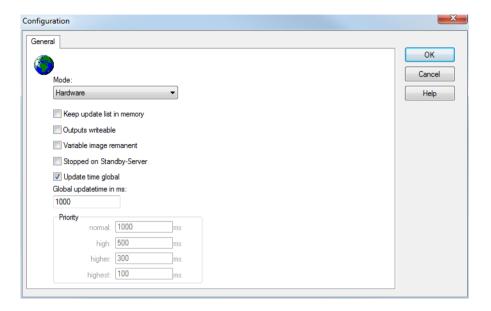

# 6.2 Settings in the driver dialog

You can change the following settings of the driver:

### 6.2.1 General

Parameters	Description
Mode	Allows to switch between hardware mode and simulation mode
	▶ Hardware:
	A connection to the control is established.
	▶ Simulation static
	No communication between to the control is established, the values are simulated by the driver. In this modus the values remain constant or the variables keep the values which were set by straton. Each variable has its own memory area. E.g. two variables of the type marker with offset 79 can have different values in the Runtime and do not influence each other. Exception: The simulator driver.
	▶ Simulation - counting
	No communication between to the control is established, the values are simulated by the driver. In this modus the driver increments the values within a value range automatically.
	▶ Simulation - programmed
	N communication is established to the PLC. The values are calculated by a freely programmable simulation project. The simulation project is created with the help of the straton Workbench and runs in a straton Runtime which is integrated in the driver. For details see chapter Driver simulation (main.chm::/25206.htm).
Keep update list in the memory	Variables which were requested once are still requested from the control even if they are currently not needed.  This has the advantage that e.g. multiple screen switches after the screen was opened for the first time are executed faster because the variables need not be requested again. The disadvantage is a higher load for the communication to the control.
Outputs writeable	Active: Outputs can be written.
	Inactive: Writing of outputs is prevented.
	Note: Not available for every driver.

Variable image remanent	This option saves and restores the current value, time stamp and the states of a data point.
	Fundamental requirement: The variable must have a valid value and time stamp.
	The variable image is saved in mode hardware if:
	<ul> <li>one of the states S_MERKER_1(0) up to S_MERKER8(7), REVISION(9), AUS(20)</li> <li>or ERSATZWERT(27) is active</li> </ul>
	The variable image is always saved if:
	▶ the variable is of the object type Driver variable
	the driver runs in simulation mode. (not programmed simulation)
	The following states are not restored at the start of the Runtime:
	▶ SELECT(8)
	▶ WR-ACK(40)
	▶ WR-SUC(41)
	The mode <b>Simulation</b> – <b>programmed</b> at the driver start is not a criterion in order to restore the remanent variable image.
Stopped on Standby Server	Setting for redundancy at drivers which allow only on communication connection. For this the driver is stopped at the Standby Server and only started at the upgrade.
	<b>Attention:</b> If this option is active, the gapless archiving is no longer guaranteed.
	Active: Sets the driver at the not-process-leading Server automatically in a stop-like state. In contrast to stopping via driver command, the variable does not receive status switched off (statusverarbeitung.chm::/24150.htm) but an empty value. This prevents that at the upgrade to the Server irrelevant values are created in the AML, CEL and Historian.
Update time global	Active: The set Update time global in ms is used for all variables in the project. The priority set at the variables is not used. Inactive: The set priorities are used for the individual variables.
Priority	Here you set the polling times for the individual priorities. All variables with the according priority are polled in the set time. The allocation is taken

	place for each variable separately in the settings of the variable properties. The communication of the individual variables are graduated in respect of importance or necessary topicality using the priorities. Thus the communication load is distributed better.
OK	Accepts settings in all tabs and closes dialog.
Cancel	Discards all changes and closes the dialog.
Help	Opens online help.

### **UPDATE TIME FOR CYCLICAL DRIVER**

The following applies for cyclical drivers:

For Set value, Advising of variables and Requests, a read cycle is immediately triggered for all drivers regardless of the set update time. This ensures that the value is immediately available for visualization after writing. Update times can therefore be shorter than pre-set for cyclical drivers.

### 6.2.2 Com

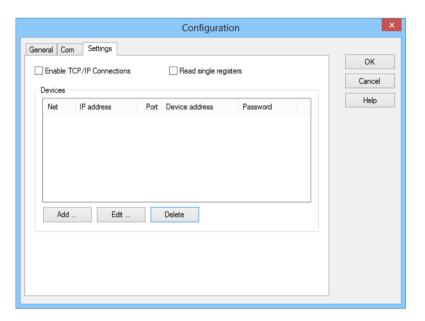

According to IEC62056, the following interface parameters are to be used:

Parameters	Value
Baud rate	300
Data bit	7
Stop bit	1
Parity	Even
Protocol	NO

## 6.2.3 Settings

The driver support both serial communication and communication via TCP/IP. Only one of the two communication types can be used per device.

Parameters	Description
Enable TCP/IP Connections	Selected: The driver communicates via TCP/IP.
Read single registers	Not selected: Driver reads the complete Table 1 from the counter.
	Selected: Driver switches to programming mode and reads each variable individually. The corresponding IEC 62056 address of the variable must be configured beforehand.
	Note: Not every counter supports the use of single registers. You can find information on this in the documentation from the respective manufacturer.
Devices	List of configured stations.
Add	Opens the dialog for adding a station.
Edit	Opens the selected configuration for editing.
Delete	Deletes selected configuration.
ОК	Accepts changes in all tabs and closes dialog.
Cancel	Discards changes and closes the dialog.
Help	Opens online help.

### **ADDING A SERIAL STATION:**

Parameters	Description
Net address	You can choose any number for allocating variables to the station in the driver. The number must be unique for each driver. This number is to be given as the network address in the address settings of the variables.
	Range 0-255
Device address	Hardware address of the device to be read from, in accordance with IEC 62056.
IP-Address	Not available for serial connection
Port	Not available for serial connection
Password	Input of a password, if required.
OK	Accepts configuration and closes dialog.
Cancel	Cancels configuration and closes dialog.

### ADDING A TCP/IP STATION:

Parameters	Description	
Net address	You can choose any number for allocating variables to the station in the driver. The number must be unique for each driver. This number is to be given as the network address in the address settings of the variables.	
	Range 0-255)	
Device address	Not available for TCP/IP connection.	
IP address	IP address of the station.	
IP port	IP port of the station.	
	Default: 1000	
OK	Accepts configuration and closes dialog.	
Cancel	Cancels configuration and closes dialog.	

### 6.3 Communication

The driver communicates in mode Mode C, "programming mode". It can therefore address all data points in the counter. Any access password that may be necessary for this must be configured in the driver configuration for each counter.

The variable name can be configured via a driver specific property. If this property is empty, the variable identification is used as the variable name.

The time stamp can also be rounded up or down to the value of a start or end of an adjustable interval using two driver-specific properties.

To set the time via R2 command to C003, there is the Clock Sync - BOOL area. Writing to this variable sends the command to the counter. Variables in this area are write-only; they do not contain an actual value.

# 7. Creating variables

This is how you can create variables in the zenon Editor:

### 7.1 Creating variables in the Editor

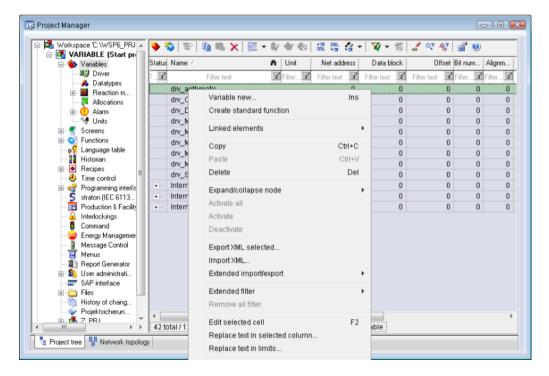

Variables can be created:

- as simple variables
- ▶ in arrays (main.chm::/15262.htm)
- ▶ as structure variables (main.chm::/15278.htm)

#### **VARIABLE DIALOG**

To create a new variable, regardless of which type:

1. Select the New variable command in the variables node in the context menu

- 2. The dialog for configuring variables is opened
- 3. configure the variable

4. The settings that are possible depends on the type of variables

Parameters	Description
Name	Distinct name of the variable. If a variable with the same name already exists in the project, no additional variable can be created with this name.
	Maximum length: 128 characters
	Attention: The characters # and @ are not permitted in variable names. If non-permitted characters are used, creation of variables cannot be completed and the Finish button remains inactive.
Drivers	Select the desired driver from the drop-down list.
	<b>Note:</b> If no driver has been opened in the project, the driver for internal variables (Intern.exe (Main.chm::/Intern.chm::/Intern.htm)) is automatically loaded.
Driver object type (cti.chm::/28685.h tm)	Select the appropriate driver object type from the drop-down list.

Data type	Select the desired data type. Click on the button to open the selection dialog.
Array settings	Expanded settings for array variables. You can find details in the Arrays chapter.
Addressing options	Expanded settings for arrays and structure variables. You can find details in the respective section.
Automatic element activation	Expanded settings for arrays and structure variables. You can find details in the respective section.

#### **INHERITANCE FROM DATA TYPE**

Measuring range, Signal range and Set value are always:

- derived from the datatype
- Automatically adapted if the data type is changed

Note for signal range: If a change is made to a data type that does not support the set signal range, the signal range is amended automatically. For example, for a change from INT to SINT, the signal range is changed to 127. The amendment is also carried out if the signal range was not inherited from the data type. In this case, the measuring range must be adapted manually.

# 7.2 Addressing

Property	Description
Name	Any name may be chosen. ATTENTION: the name must be unique within every control system project.
Identification	The identification field is used for addressing. Example: 1.2.0
Net address	Bus address or net address of the variable.
	This address refers to the bus address in the connection configuration of the driver. This defines the station, on which the variable resides.
Data block	not used for this driver
Offset	not used for this driver
Alignment	not used for this driver
Bit number	not used for this driver
String length	Only available for String variables: Maximum number of characters that the variable can take.
Driver object type	Depending on the employed driver, an object type is selected during the creation of the variable; the type can be changed here later.
Data type	Data type of the variable, which is selected during the creation of the variable; the type can be changed here later.
	ATTENTION: If you change the data type later, all other properties of the variable must be checked and adjusted, if necessary.

# 7.3 Driver objects and datatypes

Driver objects are areas available in the PLC, such as markers, data blocks etc. Here you can find out which driver objects are provided by the driver and which IEC data types can be assigned to the respective driver objects.

## 7.3.1 Driver objects

The following object types are available in this driver:

Driver object type	Channel type	Read / Write	Supported data types	Description
Input	10	R	UDINT, DINT, LREAL, STRING, DATE_AND_TIME,	
Driver variable	35	R/W	BOOL, SINT, USINT, INT, UINT, DINT, UDINT, REAL, STRING	Variables for the statistical analysis of communication.  Find out more in the chapter about the Driver variables

### 7.3.2 Mapping of the data types

All variables in zenon are derived from IEC data types. The following table compares the IEC datatypes with the datatypes of the PLC.

Control	zenon	Data type
-	BOOL	8
-	USINT	9
-	SINT	10
-	UINT	2
-	INT	1
UDINT	UDINT	4
DINT	DINT	3
-	ULINT	27
-	LINT	26
-	REAL	5
LREAL	LREAL	6
STRING	STRING	12
-	WSTRING	21
-	DATE	18
-	TIME	17
DATE_AND_TIME	DATE_AND_TIME	20
-	TOD (Time of Day)	19

Data type: The property Data type is the internal numerical name of the data type. It is also used for the extended DBF import/export of the variables.

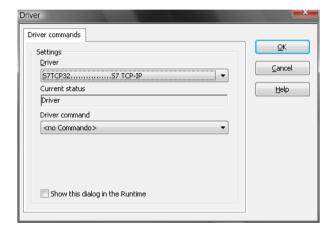

## 8. Driver commands

This chapter describes standard functions that are valid for most zenon drivers. Not all functions described here are available for every driver. For example, a driver that does not, according to the data sheet, support a modem connection also does not have any modem functions.

Driver commands are used to influence drivers using zenon; start and stop for example. The engineering is implemented with the help of function <code>Driver</code> commands. To do this:

- create a new function
- ▶ select Variables -> Driver commands
- ► The dialog for configuration is opened

Parameters	Description
Drivers	Drop-down list with all drivers which are loaded in the project.
Current state	Fixed entry which has no function in the current version.
Driver commands	Drop-down list for the selection of the command.
> Start driver (online mode)	Driver is reinitialized and started.
<pre>&gt; Stop driver (offline mode)</pre>	Driver is stopped. No new data is accepted.  Note: If the driver is in offline mode, all variables that were created for this driver receive the status switched off (OFF; Bit 20).
Driver in simulation mode	Driver is set into simulation mode.  The values of all variables of the driver are simulated by the driver. No values from the connected hardware (e.g. PLC, bus system,) are displayed.
▶ Driver in hardware mode	Driver is set into hardware mode.  For the variables of the driver the values from the connected hardware (e.g. PLC, bus system,) are displayed.
▶ Driver-specific	Enter driver-specific commands. Opens input field in order to

	command	enter a command.
•	Activate driver write set value	Write set value to a driver is allowed.
•	Deactivate driver write set value	Write set value to a driver is prohibited.
•	Establish connection with modem	Establish connection (for modem drivers) Opens the input fields for the hardware address and for the telephone number.
•	Disconnect from modem	Terminate connection (for modem drivers)
	ow this dialog in the	The dialog is shown in Runtime so that changes can be made.

#### DRIVER COMMANDS IN THE NETWORK

If the computer, on which the driver command function is executed, is part of the zenon network, additional actions are carried out. A special network command is sent from the computer to the project server, which then executes the desired action on its driver. In addition, the Server sends the same driver command to the project standby. The standby also carries out the action on its driver.

This makes sure that Server and Standby are synchronized. This only works if the Server and the Standby both have a working and independent connection to the hardware.

## 9. Error analysis

Should there be communication problems, this chapter will assist you in finding out the error.

## 9.1 Analysis tool

All zenon modules such as Editor, Runtime, drivers, etc. write messages to a joint log file. To display them correctly and clearly, use the Diagnosis Viewer (main.chm::/12464.htm) program that was also installed with zenon. You can find it under *Start/All programs/zenon/Tools 7.11 -> Diagviewer*.

zenon driver log all errors in the log files. The default folder for the log files is subfolder Log in directory ProgramData, example:

C:\ProgramData\zenon\zenon7.11\LOG for zenon Version 7.11. Log files are text files with a special structure.

Attention: With the default settings, a driver only logs error information. With the Diagnosis Viewer you can enhance the diagnosis level for most of the drivers to "Debug" and "Deep Debug". With this the driver also logs all other important tasks and events.

In the Diagnosis Viewer you can also:

- follow currently created entries live
- customize the logging settings
- change the folder in which the log files are saved

#### Hints:

- 1. In Windows CE even errors are not logged per default due to performance reasons.
- 2. The Diagnosis Viewer displays all entries in UTC (coordinated world time) and not in local time.
- 3. The Diagnosis Viewer does not display all columns of a log file per default. To display more columns activate property Add all columns with entry in the context menu of the column header.
- 4. If you only use Error logging, the problem description is in column Error text. For other diagnosis level the description is in column General text.
- 5. For communication problems many drivers also log error numbers which the PLC assigns to them. They are displayed in Error text and/or Error code and/or Driver error parameter (1 and 2). Hints on the meaning of error codes can be found in the driver documentation and the protocol/PLC description.
- 6. At the end of your test set back the diagnosis level from Debug Or Deep Debug. At Debug and Deep Debug there are a great deal of data for logging which are saved to the hard drive and which can influence your system performance. They are still logged even after you close the Diagnosis Viewer.

### Information

You can find further information on the Diagnosis Viewer in the Diagnose Viewer (main.chm::/12464.htm) chapter.

### 9.2 Check list

Is the station connected to the power supply?
Are the participants available in the TCP/IP network
Can the station be reached via the PING command?
Can the station be reached on the corresponding port via TELNET?
Are the station and the PLC connected with the right cable?
Was the right COM port selected?
Do the communication parameters match (Baud rate, parity, start/stop bits,)
Is the COM port blocked by another application
Did you configure the net address correctly, both in the driver dialog and in the address properties of the variable
Is the correct object type used for the variable?
Does the addressing of the variable match the one in the station?
Use the DiagViewer for further analysis -> Which messages does it show
